The measurement of serum ferritin and transferrin saturation are the most commonly used tests for evaluating iron deficiency with low ferritin concentrations reflecting iron depletion (1). One cause of iron deficiency is the over-production of red blood cells, as evident in most patients with the myeloproliferative neoplasm of polycythemia vera (PV) (2), a malignancy in which there is constitutive activation of erythropoietin receptor signalling pathway due to the acquisition of the $JAK2\, p.V617F$ mutation.

The current World Health Organization (WHO) criteria for PV diagnosis are gender-specific raised hemoglobin or hematocrit levels, tri-lineage bone marrow hypercellularity, the presence of the $JAK2\, p.V61F$ (acquired in more than 95% of cases) or exon 12 mutations, and a low serum erythropoietin concentration (3).

Additionally, these guidelines also detail the entity of masked PV, in which an iron deficiency due to the enhanced red blood cell proliferation results in an apparently normal presenting hemoglobin concentration, the diagnostic principles of which have subsequently been validated (4).
Despite subnormal serum ferritin not being a diagnostic requirement for PV, a low ferritin level in the absence of other features of PV has become a sporadic trigger for requesting JAK2 p.V617F molecular analysis. In order to address the clinical value and laboratory impact of such requests, a retrospective audit was performed on all JAK2 p.V617F requests received at a molecular diagnostics centre for hematological malignancies.

From January 2006 to December 2017 inclusive, 15562 diagnostic requests for JAK2 p.V617F mutation analysis were received. Of these, 64 requests (0.4%) were received with the only clinical details provided on the request form of a subnormal serum ferritin (normal range 23–393 ng/mL). The median age was 58 years and comprised 42 males and 22 females. Using a standardised allele-specific PCR screening assay (5) capable of detecting a 2% mutant allele burden and unchanged throughout the audit period, the JAK2 p.V617F mutation was not detected in any of these 64 patients.

Which patients to screen for the myeloproliferative neoplasm associated mutations of JAK2, CALR and MPL requires careful consideration in order to optimise laboratory resources (6,7). While the number of requests for JAK2 p.V617F mutation in patients with low serum ferritin does not appreciably impact on overall laboratory workload, reflexive screening for the JAK2 p.V617F mutation in patients with isolated subnormal ferritin levels and no further evidence of PV or masked PV appears inappropriate.
